First AST-aware masking for DLLMs → **+13.3% on HumanEval+**, narrows gap with autoregressive models

## 🔗 Motivation

Diffusion-based LLMs (DLLMs) struggle with **syntactic precision** in code generation. Standard random token masking:

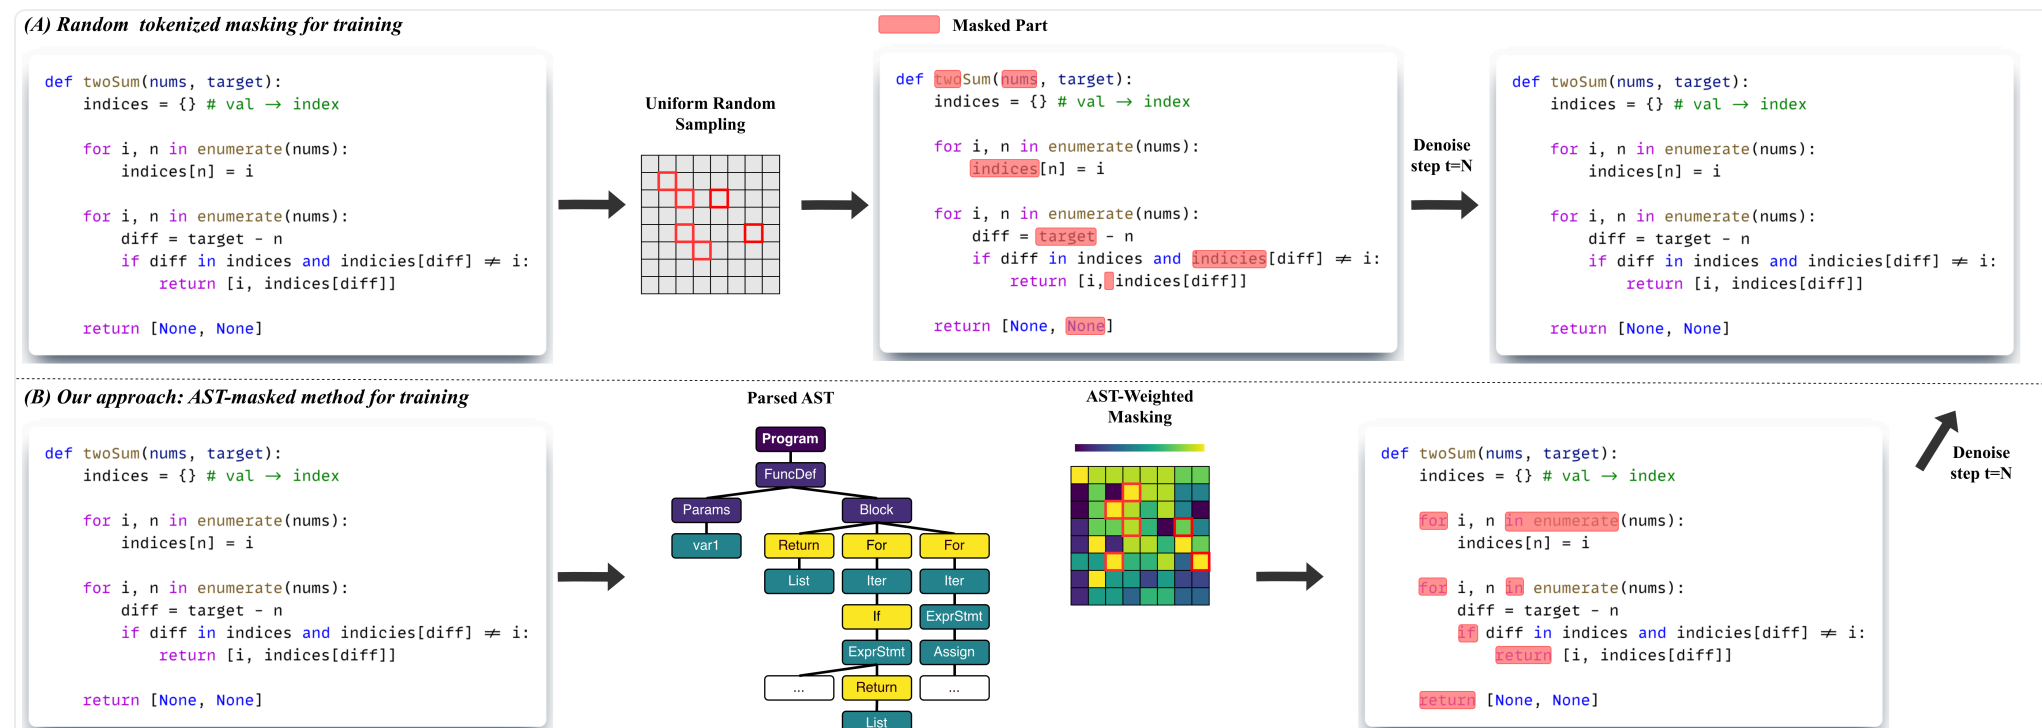

- Ignores syntactic boundaries during denoising
- Fails to capture long-range hierarchical dependencies
- Treats all tokens equally — but they are not

### CORE INSIGHT

*“For code, noise should not be purely stochastic — structural priors enable DLLMs to learn program-level dependencies.”*

## 🔗 Method: AST-Guided Masking

TreeDiff parses code into an **Abstract Syntax Tree (AST)** and uses it to guide which tokens to mask — targeting structurally critical nodes.

## 🔗 Region-specific Corruption

**Prompt** Kept intact (semantic conditioning)

**Reasoning** Random token masking

**Code** AST-weighted masking

### GOAL

*Preserve semantic conditioning while injecting structural noise into code regions.*

## 🔗 AST Node Weighting

| Category     | Examples           | Weight      | Purpose           |
|--------------|--------------------|-------------|-------------------|
| Skeletal     | Imports, Constants | 0.15        | Preserve skeleton |
| Data Flow    | Assigns, Calls     | 0.42        | Moderate priority |
| Conditionals | if, elif, else     | 0.58        | Core logic        |
| Control Flow | for, while, return | <b>0.60</b> | Highest priority  |

## 📊 Main Results (Pass@1 %)

|                                                                              |                                                                    |

## 🔗 Ablation: Masking Granularity

| HumanEval (HE / HE+) |  |             |             |
|----------------------|--|-------------|-------------|
| Strategy             |  | T=256       | T=512       |
| Random Masking       |  | 39.6 / 35.4 | 38.4 / 32.3 |
| AST (Span)           |  | 40.9 / 36.6 | 40.2 / 36.6 |
| AST (Node)           |  | 42.1 / 37.2 | 40.2 / 36.6 |
| MBPP (MBPP / MBPP+)  |  |             |             |
| Strategy             |  | T=256       | T=512       |
| Random Masking       |  | 52.9 / 43.9 | 41.5 / 32.8 |
| AST (Span)           |  | 51.6 / 42.9 | 39.7 / 31.5 |
| AST (Node)           |  | 52.9 / 44.9 | 42.3 / 33.3 |

### Why Node-level > Span-level?

## 🔗 Robustness Analysis

Random masking accumulates syntactic/logical drift at T=512. TreeDiff remains stable (~0.1%) by anchoring control-flow and skeleton nodes.

## 🔍 Generation Trajectory Analysis

**Task:** Max nesting depth of parentheses (HumanEval/6), Step 110/256.

## <> Generated Code Comparison

HumanEval/6 — Nested parentheses depth:

|                                                                                                                                                                        |                                                                                                                                      |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>TreeDiff</b><br>for char in group:<br>if char == '(':<br>stack.append(char)<br>max_depth = max(max_depth, len(stack))<br>elif char == ')':<br>if stack: stack.pop() | <b>Random Masking</b><br>count = 0<br>for char in group:<br>if char == '(':<br>count += 1<br># Fails to track<br># nested peak depth |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|

## 🔗 Why TreeDiff Works

- Random masking **breaks syntactic anchors** — the model loses structural landmarks
- Span masking **removes too much local context** — entire subtrees vanish
- TreeDiff **masks high-influence AST nodes** while preserving surrounding code structure

## ☆ Key Contributions

- First AST-aware masking** for DLLMs in code generation
- 13.3% relative improvement** on HumanEval+ vs random masking
- Trained on **150K** long code reasoning samples
- Negligible overhead: AST parsing is O(L)

## 🔗 Conclusion

TreeDiff addresses a fundamental limitation: **random masking ignores code structure**. By aligning corruption with AST hierarchy, the model learns programming language compositionality, reconstructing programs that respect grammatical boundaries and capture long-range dependencies.

**Impact:** Structural priors unlock DLLMs for code — TreeDiff narrows the gap between diffusion and autoregressive paradigms.

**Setup:** LLaDA-8B backbone · 8x NVIDIA A100 · LoRA (r=64, alpha=128) · 4096 max tokens · LR 5e-5 · Benchmarks: HumanEval/+, MBPP/+

## ⚠️ Limitations & Next Steps

- Long iterative denoising can be slow for very long traces (capped at 1024 tokens)
- Current setup uses LoRA due to 8xA100 memory constraints
- Next: faster inference schedules, broader language coverage, stronger backbones

## 🔗 Experimental Setup

|                       |                                  |
